(1) Field of the Invention The invention relates to the fabrication of integrated circuit devices, and more particularly, to a method of creating a so-called finFET device, having a three-dimensional conduction channel. (2) Description of the Prior Art Advanced integrated circuits use a three-dimensional layout where the conductive elements are arranged in a vertical direction as well as in a horizontal direction. For further scaling down of feature sizes of semiconductor devices, the FET device, in particular, has a plurality of fins, which are fin-shaped bodies of semiconductor material that are stacked on top of each other, extending in the same plane as the substrate surface and being separated from each other by isolation regions. An active region is located between a pair of isolation regions. An example for such a three-dimensional integrated circuit is the so-called finFET device, the structure and manufacturing method for which are disclosed in U.S. Pat. No. 6,413,802 (Kwok, et al.). In this patent, a plurality of spaced apart trenches are formed in a monocrystalline silicon substrate. Within each of these trenches is a monocrystalline silicon island. A thin monocrystalline silicon layer is deposited over the upper surfaces of the monocrystalline silicon islands and the trench walls, to thereby form a three-dimensional structure, and to provide electrical insulation between the monocrystalline silicon islands. An insulating layer is formed over the three-dimensional structure, followed by the formation of a gate stack on the insulating layer. FinFET devices have the advantage of a high drive current capability. Furthermore, they can be formed at a small lateral area. For increasing the drive current and at the same time reducing the overall area of a device, a fin structure is preferably formed for the channel region of the FET device. Advantages of the fin structure are the higher electron and
