Q: Why is a subset of a union of two disjoint sets a subset of a single set? Let  $M \subseteq N \subseteq P$ . Let  $M \subseteq Q$  and  $N \cap Q = \emptyset$ . Why must  $M \subseteq P$ ? I understand why  $M \subseteq N$ , because one set is a subset of the other, and you can construct the subset by removing the things that are not in both sets. I also understand why  $M \subseteq P$ , because  $N$  and  $P$  are disjoint sets, so any subset of the first is a subset of the second and vice versa. But that doesn't really work for  $M \subseteq N \cap Q$ . I can construct  $M$  by making a subset of  $N$  and then adding the things that aren't already in  $Q$  but this doesn't imply that  $M \subseteq P$ . A: You have assumed that  $N \cap Q = \emptyset$ , but you haven't used this. It is true, but you have made no assumptions. Thus  $Q = N \cup Q$  So  $Q = M \cup (N \cap Q)$  But  $M \subseteq N$ , so  $M \cup (N \cap Q) = (M \cup N) \cap Q = M \cap Q \subseteq P \cap Q = \emptyset \cap Q = \emptyset$ , which means that  $M \subseteq P$  At a glance Key facts Hotel size This hotel has 77 rooms This hotel is arranged over 2 floors Arriving/leaving Check-in time 2 PM-11:30 PM Check-out time is 11:30 AM Express check-in/out Hotel description Ofiri is a small place in the Trg Dobre Vite, our staff are ready to assist you and to show you the sights of Koprivnica. ### What's New in the?

Developments in the treatment of acute myelogenous leukemia (AML) and the need to maintain long term remission using a cytosine arabinoside-induced complete remission (CR) and consolidation phase post-induction chemotherapy resulted in the development of autologous stem cell transplantation (ASCT) for AML. The major advantage of ASCT is that the preparative regimen is able to both treat and purge AML in the donor as well as potentially the recipient. The toxicity of preparative regimens is mild with significant reduction in the morbidity associated with the procedure. Current preparative regimens for AML include myeloablative irradiation, a variety of myeloablative chemotherapies, including high dose cytosine arabinoside (HD-Ara-C) based regimens and fludarabine monotherapy. These regimens are performed with the intent of achieving a high rate of CR and CR duration as well as increased event-free survival (EFS) and overall survival (OS) for patients with AML. Unfortunately, significant toxicities are encountered with these myeloablative regimens. There are a number of subsets of AML including those with intermediate-high blast counts (ie greater than 10%), those with an unfavorable cytogenetic profile, relapsed AML, and acute promyelocytic leukemia (APL) in both the first and relapse/refractory settings. The identification of those AML subsets has permitted an increase in the intensity and number of patients being entered on clinical trials, which have led to a stepwise increase in the number of patients achieving a CR from 30% in the 1970's to 61% in 1987 and in 2006 to 88% in the UK. However, there are still large numbers of patients who are not being treated. There is a disparity between the number of patients who are being entered on clinical trials compared to those being treated with conventional protocols. A proportion of patients who are treated are failing treatment and do not survive. For this reason, intensification of protocols, including the use of high dose therapy with or without ASCT, is being investigated. ASCT itself is associated with significant morbidity and, until recently, has been a high intensity treatment. However, the introduction of the reduced intensity conditioning (RIC) regimens has allowed a significant proportion of eligible AML patients to undergo successful allogeneic SCT. It is recognized that RIC regimens are less toxic than myeloablative
